AUTHOR: Morachevskiy, T. M. (Candidate of technical sciences)

TITLE: Study of the strength properties of the aluminum alloys AV-T1, AD33-T1, D16-T, and V92-T under high speeds of load application

SOURCE: ASIA SSSR. Institut stroitel'nykh konstruktsiy. Stroitel'nyye konstruktsii iz alyuminiyevykh splavov, no. 2, 1963, 41-47

TOPIC TAGS: aluminum alloy, aluminum alloy tensile strength, aluminum alloy bending strength, AV-T1 alloy, AD33-T1 alloy, D16-T alloy, V92-T alloy, alloy strength load speed dependence, Kater pendulum

ABSTRACT: The observed mechanical strength of materials is a function of the speed of application of the load. Information in the literature, however, concerning the changes in strength of aluminum alloys under various load application speeds is very limited. Consequently, the author investigated the strength properties of certain aluminum alloys designed for use in construction (AV-T1, AD33-T1, D16-T and V92-T). The V92-T alloy samples were in the form of 20-mm thick sheets; the others were in the form of pressed shapes with a beam thickness of more than 14 mm. Tensile strength tests were performed on cylindrical samples 5 mm in diameter and 50 mm in length; bend tests were made on prismatic samples with a

Card 1/6

ACCESSION NR: AT4010742

10X10 mm cross section with a 2X2 mm incision and distance between supports of 50 mm. A total of 130 samples were tested, of which three-fourths were shock-tested, while the remainder were studied under slow application of load. The dynamic tests were made on a type PSVD-1000 pendulum-type test instrument (Kater pendulum) (Figure 1), which has interchangeable devices for tensile-tests of cylindrical samples and bend tests of prismatic samples at not less than two different load (stress) speeds within the limits of the possible rate of fall of the pendulum (2 to 5 meters/second). The test results were recorded according to the final pendulum position, indicating the effort expended on the destruction of the sample, with simultaneous photography of the oscillograms reproducing the breakdown process. Figures 2 and 3 of the Enclosure show characteristic oscillograms obtained with the aid of this test arrangement. Static tests for tensile strength were conducted on an IM-4R machine with a deformation rate of 1.3 mm/min and with mechanical recording of the force-deformation diagram. Static bend tests were made on a ZPM (East German) device having a deformation speed of 0.6 mm/min and mechanical recording of the force-deformation diagram. It was found that under shock loads (stresses) the strength properties of aluminum alloys of different types change differently. When testing the samples for tensile strength, a maximum increase in the safety factor (k_s) was obtained for alloys of medium strength AV-T1 and AD33-T1, for which $k_s \approx 1.25$ at t_{max} (time elapsing from the beginning of the application of the load to the moment it reaches its greatest value) = 1.3-1.5 micro-

Card 2/6

ACCESSION NR: AT4010742

seconds. For high-strength alloy D16-T and self-hardening alloy V92-T, the strength increase factor was considerably lower, and at $f_{max} = 1.4-2.1$ microseconds is only 1.03-1.0). The k_s factors obtained on the basis of the bend-test results were close to those for tensile strength tests. The yield point factors k_y , characterizing the increase in the yield point limit under shock loads, in the case of the AV-T1 and AD33-T1 alloys had values close to the k_s for these same alloys; for D16-T and V92-T, the k_y factors were found to be higher than the k_s (1.15 and 1.36, respectively). Original article has: 2 tables and 6 figures.

TITLE: An Active Influence Upon the Weather (Aktivnoye vozdeystviye na pogody)

PERIODICAL: Priroda, 1958, ^{4?} Nr 9, pp 85-88 (USSR)

ABSTRACT: A survey is given of American, French and Japanese experiments and achievements in rain-making, weather modification and the warding-off of hail. The effect of the explosion of hydrogen bombs on the weather is doubted, as the speed of the explosion prevents any influence on the weather process beyond an area of 30 square km in the case of a single bomb. The effect of remaining ionized dust and other fall-out has not yet been sufficiently studied. Soviet research and experiments in weather modification for the benefit of agriculture and aviation is centered mainly in the Leningradskiy institut eksperimental'noy meteorologii /LIEM/ (Leningrad Institute of Experimental Meteorology), the Glavnaya geofizicheskaya observatoriya im. Voyeykova /GGO/ (Main Geophysical Observatory im. Voyeykov), the Tsentral'naya aerologicheskaya observatoriya/

TsAO/ (Central Aerological Observatory), the Gosudarstvennyy nauchno-issledovatel'skiy institut Grazhdanskogo vozdušnogo flota (State Scientific Research Institute of the Commercial Air Lines) and other organizations. In 1949, Nikandrov, V.Ya. with his group succeeded in producing rain from cumulus and strato-cumulus clouds in 11 out of 15 trials. The methods employed are based on the artificial formation of crystallization nuclei by the spraying of CO₂, AgI and other agents into clouds to effect a disintegration of the cloud. Dry ice for crystallization nuclei is used mostly. The prevention of hail formation was successfully tried in 1956. There are 5 photos and 8 references, 3 of which are Soviet.

TITLE: The Effectiveness of CO₂-Particles and AgI-Fume for the Dispersion
of Supercooled Lower Clouds and Fogs

PERIODICAL: Tr. Arkt. i antarkt. n.-i. in-ta, 1959, Vol. 228, pp. 135-145

TEXT: The authors report briefly on the mechanism of the artificial crystal-
lization of a supercooled droplet cloud or fog by means of dry carbon dioxide ice
and AgI-fume. The appearance of crystals in the cloud causes the diffusion of the
water vapor from the droplets to the crystals and leads to rapid growth of the
latter, which causes the dispersion process of the cloud and fog. Twenty-five
research flights were carried out for clarifying some questions of the application
method of AgI and dry CO₂ during treatment the clouds and fogs with them; the
flights served to determining the optimum expenditure of the reagent. The tests
were performed in the Arctic region of Tadibe-Yakhi. The equipment and facilities

The Effectiveness of CO₂-Particles and AgI-Fume for the Dispersion of Supercooled Lower Clouds and Fogs

are described which were installed in the aircraft for producing the dry CO₂-granules, the AgI-fume, and for photographing the clouds treated. Uniform inter-nal clouds with the vertical thickness up to 500 m were treated. The schemes are presented of sounding and flight during the action, and the course of maneuvering of the aircraft according to the scheme mentioned is described. A compilation table of the action results from 20 tests is added. On the basis of the data obtained, the authors conclude as follows: 1) the action of dry CO₂ upon clouds and fogs is ineffective at the temperature of the latter higher than -4°C; 2) the vertical maximum thickness of the cloud capable of being dispersed by spreading CO₂ from one level amounts to 600 m. It is pointed out that under arctic conditions an accelerated process of phase transformations in the clouds is observed in comparison with other regions; this is explained by the lower water content of the clouds. Data are presented which characterize the cloud transformation process until full destruction due to dry CO₂ treatment under various meteorological conditions. A graph is given of the dependence of the dry CO₂ expenditure per 1-km flight on the cloud thickness when treatment is performed from one level.

The Effectiveness of CO₂-Particles and AgI-Fume for the Dispersion of Supercooled Lower Clouds and Fogs

A table is presented of the specific CO₂ dosages applied by various investigators in dependence on the cloud thickness. The results of two tests are described in detail, which were performed in the Chelyuskin Cape region, and conclusions are drawn from the results of all other tests. One of the tests on the action of AgI upon layered clouds in the Tadibe-Yakhi region is described more in detail. Micro-photographs are presented of the ice crystal samples in a layered cloud after the treatment of a supercooled cloud with AgI-fume.

TITLE: The Equipment for the Treatment of Supercooled Clouds and Fogs From an Aircraft

PERIODICAL: Tr. Arkt. i antarkt. n.-i. in-ta, 1959, Vol. 228, pp. 155-161

TEXT: An aircraft fume-generator and the unit producing dry CO₂-granules immediately from balloons, installed in the aircraft are described. In an introduction, the present generators for sublimating AgI and the units for granulating dry CO₂ are reviewed. Their disadvantages and the requirements are considered which must be met by the modern units. The AgI-fume generator developed by the authors in 1956 is described in detail. The fundamental schematic diagram and the technical data of the generator are presented as well as the thermal balance of the device and the absolute values of the heat consumption in kcal/hour. The operational principle is described of the unit for producing granules of dry CO₂ directly from liquid CO₂ by throttling the latter through a delivery throttling

Card 1/2

ring with continuous pressure drop in the diffuser, which leads to the formation of a solid-particle stream out of the aircraft; the particles are sphere-shaped mainly with a radius of 0.4 - 0.6 cm. The size distribution curve is added of the CO₂-granules obtained from the airborne unit, and the unit operation duration is stated depending on the output and the quantity of the balloons with liquid CO₂ engaged simultaneously. The authors assume that it is expedient to install the developed aircraft fume-generator and the airborne unit for producing dry CO₂-granules in the aircraft of ice survey for the purpose of dispersing the lower clouds and fogs in the Arctic region.

TITLE: The Results of Combined Investigations of the St-Sc
Clouds and of Fog in the Arctic

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya geofizicheskaya,
1960, No 1, pp 107-114

TEXT: A 1956 summer expedition to the Central Arctica investigated the microphysical structure of clouds and fog. The present paper reports the results of simultaneous measurements of the water content of stratus clouds and their humidity, temperature, transparency and the drop-size distribution. Seventy vertical soundings were carried out in St-Sc clouds and in fog and measurements of the drop size were made at height intervals of 20, 50 and 100 m. Some horizontal measurements of cloudiness were also carried out. An IL-12 aircraft made 37 flights over the shores and water area of the Karsk Sea. Temperatures were measured by means of a screened thermometer in the aircraft with an automatic recorder K4-5M (this instrument was used also to record the air pressure). Temperature was measured also (together with humidity)

Card 1/3

The Results of Combined Investigations of the St-Sc Clouds and of Fog in the Arctic

using a thermohygrometer LO-3²¹. The water content was found using Zaytsev's instrument (Ref 2). Drops were measured by micro-photography (Refs 1, 3), with a magnification of 300. A new photoelectric instrument SIP-3²⁴ (Fig 1) was used to measure the transparency of clouds in the visible region. The instrument SIP-3 measured the meteorological visibility range between 26 and 500 m with an error not exceeding 20% (when its geometrical base was 13 m). The data obtained were analysed and the results are given in Figs 2-6. The vertical distribution of the water content (q , g/m³) and the visibility range (S , m) in fog are shown in Fig 2. Fig 3 gives the size histograms of the fog drops. The vertical distributions of the water content (q), the visibility range (S) and temperature (t , °C) for stratus clouds are given in Fig 4, and for strato-cumulus clouds in Figs 5 and 6 (Fig 5 includes also the effective dimensions of drops). In stratus and strato-cumulus clouds, whose vertical thickness was of the order

Card 2/3 ✓

TITLE: Experimental investigation of the value of the evaporation coefficient for aqueous solutions of surface-active materials

SOURCE: Leningrad. Universitet. Problemy* fiziki atmosfery*, no. 2, 1963, 151-154

TOPIC TAGS: meteorology, surface-active material, atmospheric physics, evaporation coefficient, cloud physics, cloud dispersal, fog dispersal, cloud evaporation rate, chemical cloud dispersal

ABSTRACT: Investigation of the kinetics of evaporation and condensation of aqueous solutions of surface-active materials are of interest because of their possible use as reagents for the dispersal of clouds and fogs. The authors have used the T. Alty method for determination of the evaporation rate of pure water (Phil. mag, vol. 15, No. 82, 1933; Proc. Roy. Soc., vol. 149, No. 104, 1935) in an experimental investigation of the evaporation coefficients of several types of aqueous solutions of surface-active materials. Description of the apparatus used, which involved a force pump, manometer, and thermostat, is limited to two sentences and a photograph. The first step in the experiment was to determine the coefficient of evaporation of water. Five experiments were made, giving a mean value of the coefficient $\alpha = 0.0368$, which agrees well with Alty's value ($\alpha = 0.037$). This was

Card 1/2

ACCESSION NR: AT4G33375

followed by measurement of the evaporation coefficient of two bromides of an ammonium amide base with the radicals $R = C_2H_5$, $R = C_3H_7$, in the form of solutions with concentrations of 0.1, 0.25, 0.5, and 1% by weight. Five or six measurements of the evaporation coefficient were made for each concentration of the solution. The results revealed that with an increase in the concentration the evaporation coefficient attains a minimum value at a concentration of 0.25-0.5% and thereafter does not change. This can mean that a further increase in concentration does not influence surface properties. The derived decrease in the evaporation coefficient does not correspond numerically to the decrease in the evaporation rate of these solutions. Orig. art. has: 2 figures, 2 formulas, and 2 tables. ✓

ABSTRACT: An experiment was carried out with particles of silver iodide tagged with atoms of radioactive iodine I^{131} . The objective was a study of the effectiveness of both ordinary AgI and tagged AgI^{131} particles. The two were sublimated under identical conditions and their crystalline structure was identical. This was confirmed by an electron microscope analysis of samples of the particles. The experiments were made in a cold chamber measuring 70 x 70 x 70 cm; temperature in the chamber was reduced to -15° . The liquid water content of the fog, samples of drops and crystals were determined by ordinary methods; fog transparency was measured photoelectrically.

TITLE: Power parameters and dynamic behavior of a multiple stage pneumatic drive for automatic systems

SOURCE: AN SSSR. Institut avtomatiki i telemekhaniki. Pnevmoavtomatika (Pneumatic automation). Moscow, Izd-vo Nauka, 1966, 244-250

TOPIC TAGS: pneumatic device, pneumatic control system, gas compressor, air temperature, heat exchanger, expanding gas

ABSTRACT: The efficiency and response of pneumatic drives can be improved through the use of multiple stage devices. The author describes one such system, and compares its efficiency and performance with ordinary single stage drives. The pneumatic drives are frequently incorporated in automatic control system as prime movers. In this application, the piston must be capable of stopping in any position upon receiving an appropriate command. The magnitude and the direction of the displacement are determined by the magnitude and the sign of this command. Compared to ordinary reciprocating internal combustion and steam engines, this operation is quite inefficient. For isothermal expansion, the efficiency of a common single stage pneumatic drive is given by

$$\eta_T = \frac{1 - \frac{1}{\epsilon_c}}{\ln \epsilon_c}$$

Card 1/4

CC NR: AT6021752

where $\epsilon_c = P_c/P_1$ are the absolute pressure of the intake and the compressed air respectively. The closer the actual operation of the drive can approximate the isothermic conditions, the better the efficiency. Fig. 1. shows a diagram of a multiple stage pneumatic drive. The air is fed through a supply line from a compressor. The multiple stage drive consists of a number of single stage piston drives (C_1, C_2, C_n), serially connected through expanders (P_2, P_3, P_n). Each stage operates at a constant pressure difference and is supplied by compressed air, which passed through the preceding stage and expanded to a predetermined pressure in the expander. The air from the compressor enters air distributor (BP_1) of the first stage. Rotating distribution valve (PO_1) admits the air to cylinder (C_1). The passive cylinder volume is connected to expander (P_2) such that the same pressure, as in the expander is maintained in this portion of the cylinder. Pressure reduction valve (PK_2) maintains the air pressure in the expander (P_2) constant. The compressed air from (P_2) feeds through distributor (BP_2) to the next cylinder (C_2), etc. Each consecutive cylinder has a larger diameter and greater piston area to generate identical force at reduced air pressure. All piston rods are connected to the same load and move synchronously. The air distributor drive operates all distributor rotating valves in synchronously, thus providing control over the direction and the magnitude of the output displacement. The efficiency of the multiple stage drive is given by

$$\eta_r = \frac{1 - \epsilon_c^{1/\gamma}}{\ln \epsilon_c} \alpha$$

ACCESSION NR: AP4027175

F/0061/63/000/004/0085/0091

AUTHOR: Koraczewski, Marian (Captain, Engineer)

TITLE: Noctovision devices for carrying out combat operations at night and under poor visibility conditions

SOURCE: Przegląd wojsk lądowych, no. 4, 1963, 85-91

TOPIC TAGS: night combat operation, noctovision, noctovision device, image converter tube, small unit tactics, night troop training, infrared image converter, snooperscope, sniperscope, infrared viewing device, infrared transmitter, night direct fire control

ABSTRACT: Combat operations will assume an especial maneuvering character in future armed conflicts, in connection with which separate military units will have to know how to skillfully execute night marches under conditions of total darkness. They will also have to know how to carry out combat missions at various times of day or night and under poor visibility conditions caused by fog, blizzard, or smoke screen laid down by either friendly or enemy troops. Past experience shows that night operations are very difficult to execute. The majority of the troops are city-bred and are acclimated to lighted streets, with the result that they easily

Card 1/3

ACCESSION NR: AP402T175

lose their sense of direction during night operations. This deteriorates the combat readiness of the entire small unit participating in the operations. In order to offset this, modern armies are continually increasing the amount of technical equipment which aids in the carrying out of night operations. Their quality is also improving. Night viewing, or noctovision, devices are included in this group. Only infrared night viewing devices are presently being used, because devices operating in a radiation band of lesser wavelength or in ultraviolet have a shorter range. One of the basic parts of a night viewing device is a unit for the direct conversion of an invisible picture into one which the eye can see. This is the electron image converter tube. There are two basic tube types: the vacuum tube and semiconductor tube. The vacuum image converter tube has one fault in that it operates satisfactorily only in a radiation range not exceeding a wavelength of 1 micron. This type of wavelength is emitted by objects whose temperature exceeds 300C. Objects with a lower temperature have to be illuminated with an IR transmitter. This makes it easier for the enemy to pinpoint the noctovision position and engage it with fire. The semiconductor image converter tube is sensitive to IR waves of several microns in length. A special IR transmitter for illuminating the object is also necessary, although the transmission is not as intensive as in the case of the vacuum snooperscope. The range of vehicle-mounted noctoviewing devices is about 50 to 100 meters. Those intended for use with automatic weapons and individual small arms fire have a

Card 2/3

ACCESSION NR: AP4027175

range up to 200 meters. The snooperscopes used for artillery direct fire control and battlefield observations have the longest range, attaining about 600 meters. The power feed and transmitter units are very heavy. The service life of a tube in a xenon transmitter is about 1,000 hours. The diameter of a reflector of this type can be from 40 to 60 cm; the weight is from 50 to 70 kg. They can be readily detected by the enemy. The vehicle-mounted reflectors are powered by a 12 or 14 volt circuit; the individual ones are powered by a battery. Orig. art. has: 2 figures.

TITLE : Possibility of Deciding the Fertiliser Requirements of Meadow Soils by Analysis of Certain Grass Species

ORIG. PUB. : Roczn. nauk rolniczych, 1966, VII, No. 4, 1003-1044

ABSTRACT : In experiments made by the Department of Meadows and Pastures of the Higher School of Agriculture in Warsaw on mineral turf soil and on two peat bogs in which the effectiveness of fertilizers was studied, analyses were made of selected grasses: Dactylis glomerata, Festuca rubra, Anthoxanthum odoratum, Poa pratensis, Poa palustris, Festuca pratensis and Alopecurus pratensis; for mineral element content and fodder value. The greatest diversities in P and K content were found in the first three grasses, the least in the last. As a rule, on peat soils all grasses contained more K and less K and P than on mineral soil. in the Pancreas Following Trauma

Orig Pub : Sb. tr. Kurskiy med. in-t, 1956, vyp 11, 346-349

Abstract : Within six hours following intense mechanical damage of the tail of the pancreas, one observes in it hemorrhage and edema of the connective tissue. In the islands, pyknosis of the nuclei is found, as well as shrinking of the protoplasm, and absence of differentiation into cells A and F. In the noninjured parts of the gland only an intense hyperemia and suppression of secretion is found. The injured section of the gland appears

TITLE: Ferruginous Quartzites in Tuva (Zhelezistyye kvartzity
v Tuve)

PERIODICAL: Tr. Vses. aerogol. tresta, 1956, vol 2, pp 80-81

ABSTRACT: Ferruginous quartzites, chiefly magnetite varieties, have been discovered in the western part of the Sangilen Nagor'ye (upland in southeastern Tuva) among Proterozoic rocks. In addition to quartz and magnetite, garnet, cummingtonite and, more rarely, common hornblende are frequently found in these rocks. The ferruginous quartzites are intimately associated with amphibolites and garnet amphibolites containing disseminations of magnetite; these rocks give way along the strike to the ferruginous quartzites. From a study of the geologic structure of western Sangilen and of the known outcrops of ferruginous

Card 1/2

15-1957-7-9280

Ferruginous Quartzites in Tuva (Cont.)

quartzites, the author draws the following conclusions: 1) the ferruginous quartzites are clearly restricted stratigraphically; 2) they are found in the Proterozoic deposits only where the facies-profile changes in the direction of greater abundance of primary elastic sediments (sediments in the uplift that formed in shallower water); 3) the association of ferruginous quartzites with amphibolites and the microscopic data from the latter lead one to assume an indirect genetic relationship between the ferruginous quartzites and volcanic activity; and 4) the degree of metamorphism of the ferruginous quartzites in western Sanglien is not uniform in different areas, but in general it is higher than in similar formations in Karsakpay and in western and southern Sayan. Some of these quartzites contain enough iron to meet modern technological requirements.

TITLE: The Age of Ultrabasic and Alkaline Rocks of the Aldanian Shield
(Vozrast ul'traosnovnykh i shchelochmykh porod Aldanskogo shchita)

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 1, pp 168-169
(USSR)

ABSTRACT: Several massifs formed by the rocks mentioned in the title were discovered by the geologists of the organizations of the Ministerstvo geologii i okhrany nedr (Ministry of Geology and Conservation of Natural Resources) in the course of aeromagnetic and geological surveying operations. Contradictory opinions were held regarding their age (V. V. Arkhangel'skaya, A. G. Kata, S. P. Stoyalov, Refs 1,3 et al, V. M. Moralev, N. D. Zlenko, A. A. Yel'yanov, N. N. Gerakov, Ref 2). New data obtained in 1958 by N. D. Zlenko, L. I. Makhonina and A. N. Mil'te now make it possible to solve the hitherto pending problem mentioned in the title in a safe way. There is a peculiar domal structure in the Ingiliyskiy massif, in which a steep warping of the strata is observed around a Proterozoic core (simum). Its

Card 1/2

SOV/20-127-1-46/65

The Age of Ultrabasic and Alkaline Rocks of the Aldanian Shield

bedding is, however, practically horizontal and quiet over huge areas of the bordering territories. The ijolite-melteigite massif lying in the central part of the dome is surrounded by a ring of nepheline, canorinite and other syenites containing veins of carbonatites. Elsewhere in the Aldanian shield quite a similar warping of the sedimentary sinium atrata, as above described, is observed in the Konderskiy massif of ultrabasic-alkaline rocks. The specific penetration mechanics of the intrusions in question is probably responsible for the formation of specific (domal) structures, which, by the way, are by no means typical of such intrusions. Thus, it is possible today to identify the age of the entire complex with utmost safety as a late-Sinian - Precambrian (predyidomskiy). Its full autonomy from both the geological and genetic point of view is thus proven. There are 5 Soviet references.

AUTHOR: Moralevich, Yu., Engineer 25-10-37/41

TITLE: Engineering during the 6th Five-Year Plan (Tekhnika shestoy pyatiletki)

PERIODICAL: Nauka i Zhizn', 1957, # 10, pp 61-62 (USSR)

ABSTRACT: The publishing house TsK VLKSM "Molodaya Gvardiya" started to issue a new series of books dealing with the various items of the 6th Five-Year plan. The author gives a short survey on five of these books: The founding of steel is discussed in "Stal'noy potok" (The flow of steel) by I. Peshkin. The books "Teplovozy" (Locomotives) by L. Gumilevskiy and "Lokomotivy bol'shikh dorog" (Long Distance Locomotives) by G. Kulikovskaya deal with the development and electrification of railways. A. Zayats in his book "Vintokryly" (Helicopters) points out new aspects in aviation. G. I. Babat, Russian scientist and Doctor of Technical Sciences, wrote "Uskoriteli" (Accelerators), a book dealing with the importance of accelerators for making peaceful use of atomic energy.

The series will be continued by further publication of books relating to the 6th Five-Year plan, such as "Vtoraya Luna" (The Second Moon), "V nebe "TY-104" (TU-104 in the

TITLE: The Most Simple Wind-Driven Electric Station (Prosteysnaya vetroelektrostantsiya)

PERIODICAL: Tekhnika molodezhi, 1958, Nr 7, pp. 8-9, continued p. 31 (USSR)

ABSTRACT: Already in prehistoric times Man knew how to utilize windpower for his own ends. Windmills have been improved more and more. The evaluation coefficient of a modern windmill motor is about 30%. The most difficult and most complicated part of a windmill motor is the wind wheel. The author of this article describes the production of a windmill motor which is a light amateur-made device. This simple motor can be used above all for a small electric station. According to whether an auto- or tractor generator is available, it is possible to supply one or several houses with electric light. For this purpose 6- and 12 Volt electric bulbs for automobiles are used. The motor can also be used for the purpose of driving a hand-operated pump of the "Al'veyer" type or of some other system. The dimensions of the wind wheel, which must have a certain capacity, can be calculated according to the very simple formula:

The Most Simple Wind-Driven Electric Station

10/29-58-7-7/23

$N = \frac{D^2}{10}$. There follows the description of the wind wheel. Before it is finally mounted it must first be accurately balanced, because otherwise disagreeable vibrations may be caused which would render the entire device useless within a very short time. It is not possible to establish direct connection between the electric main and the generator, because the light would flicker. It is essential to use accumulators of 6 or 12 Volts according to the voltage. At the same time an auto- or tractor reverse-current relay must be connected. It is advisable to have 2 or 3 accumulators, for this would make it possible to accumulate a considerable amount of current by alternative connection. In this way the house would have a sufficient supply of electric light and the radio receiving set could be kept going. For the purpose of driving a pump the windmill motor would have to be subjected to some alterations. There are 2 figures and 1 table.

TITLE: The Birth of the Atomic Icebreaker
(Rozhdeniye atomnogo ledokola)

PERIODICAL: Tekhnika Molodezhi, 1958, V. 26, Nr 3, pp. 6-7 (USSR).

ABSTRACT: The hull was composed in the shipyard of many tons of heavy structural steel in the course of a few months and was subsequently welded electrically. The whole hull has not a single rivet. Partition walls were erected in the interior of the hull which divide the whole vessel into a vast number of individual cells amongst which are quite small rooms, but also large halls. The ship will include 900 individual rooms altogether - thus being a swimming town. Propeller shafts, as well as various equipments and machinery were still mounted on the shipyard: Generators, pumps, pipelines. The blade of an ear which has to stand great stresses is a very important part. It weighs 30 tons. A whole brigade under supervision of brigadier N. Vagin toiled at this blade. The hull is 134 m long and 27 m wide. The height is that of a five-storey house. The launching took place on December 5, viz. on the constitution day of the USSR.

The ship was docked at a pier where its construction will be completed. A few days after the launching, a swimming crane brought a 5-storey-house, viz. the main superstructure and put it on the upper deck from "bird's-eye-view". While the main superstructure was set up, fixed and installed, the second part of the superstructure was built on a pontoon, beside the icebreaker. The interior accommodation of the unusual high and large living-rooms is carried out with much care and attention. An one-man cabin, e. g. is 8 m² of seize. It is furnished like a first-class hotel room which represents a comfortable working- and living-room during day-time. A leverage actuation at night will be sufficient to put a comfortable bed, which is accommodated in a secluded niche, at the disposal of the inhabitant of the cabin. Two-man cabins, as well as the dining-room and the saloons are equipped with the same care. The latter are spacious and as high as the halls in a good club. The author also inspected the room where the atomic reactor will be located. This room is large and of great depth and reaches up to the upper deck. It is in a distance of only a few meters from the living-rooms. But, since it is surrounded by a reliable protection, it is not more dangerous than a steam-boiler. The circulating water will produce in the steam generators the steam required for the

turbines. The turbines, on the other hand, drive the generators which supply the electric propeller motors with current. This current would be sufficient to supply a motor of 44,000 HP. Hundreds of the leading enterprises of the Soviet Union deem it an honor to supply material the first atomic icebreaker. The whole lot of her equipments, installations, machinery and apparatus are finished with greatest care and precision. There is 1 figure.
